x86-64 Stack

- Region of memory managed with stack discipline
 - Memory viewed as [array of bytes](#).
 - Different regions have different purposes.
 - (Like ABI, a policy decision)

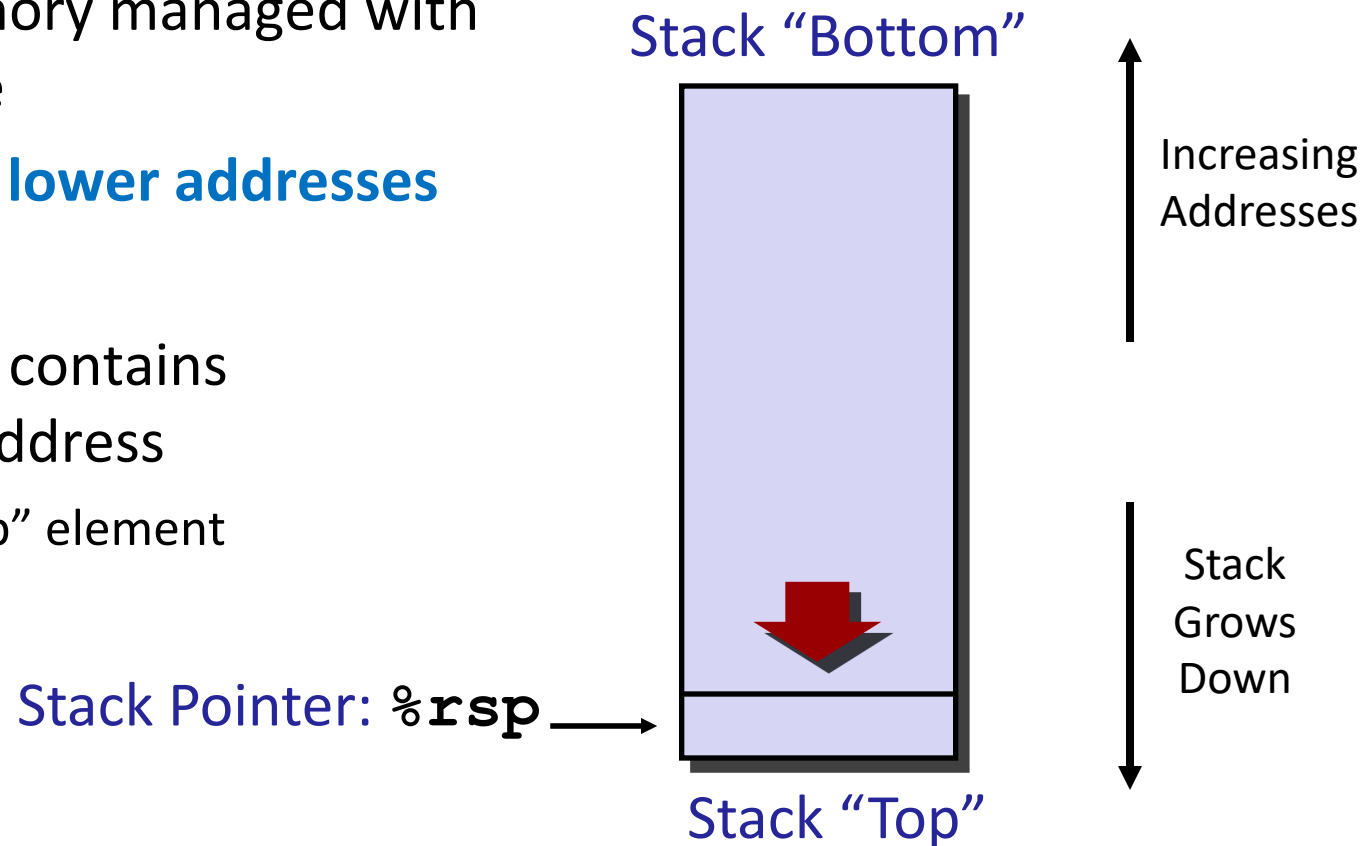

x86-64 Stack

- Region of memory managed with stack discipline

x86-64 Stack

- Region of memory managed with stack discipline
- **Grows toward lower addresses**
- Register `%rsp` contains lowest stack address
 - address of “top” element

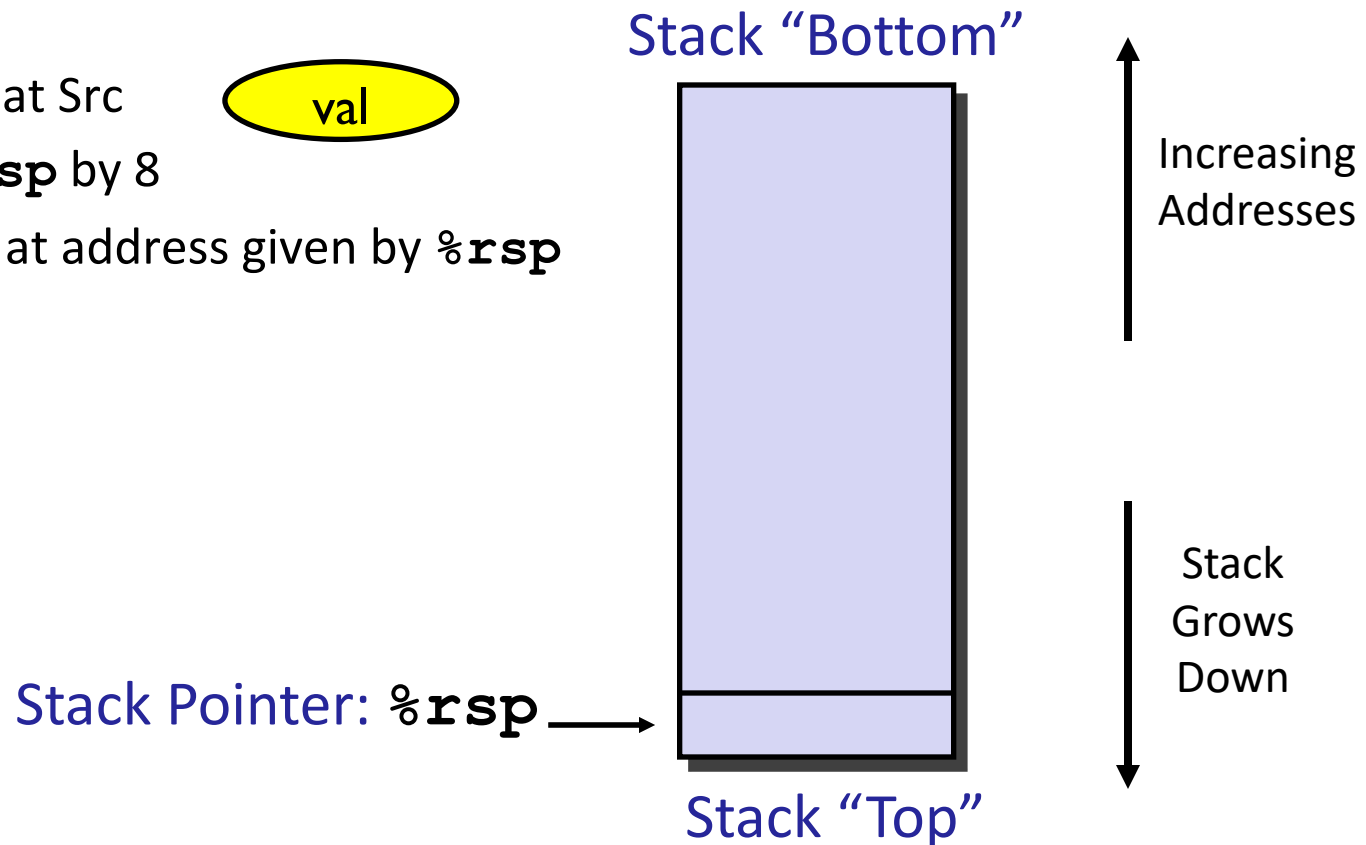

x86-64 Stack: Push

■ `pushq Src`

- Fetch operand at Src
- Decrement `%rsp` by 8
- Write operand at address given by `%rsp`

Code Examples

```
void multstore(long x, long y, long *dest)
{
    long t = mult2(x, y);
    *dest = t;
}
```

```
0000000000400540 <multstore>:
400540: push    %rbx                # Save %rbx
400541: mov     %rdx,%rbx          # Save dest
400544: callq  400550 <mult2>      # mult2(x,y)

}
```

400557: retq                       # Return
```

Procedure Control Flow

- Use stack to support procedure call and return
- **Procedure call:** `call label`
 - Push return address on stack
 - Jump to label
- **Return address:**
 - Address of the `next instruction` right after call
 - Example from disassembly
- **Procedure return:** `ret`
 - Pop address from stack
 - Jump to address

Procedure Control Flow

■ Program Counter (PC)

- Commonly called Instruction Counter (IP)
- Sometimes called Instruction Address Register (IAR), Instruction Counter

■ PC controls execution

- PC is increased after fetching an instruction
- Different instructions have different sizes (PC+=1/2/4)
- Holds the memory address of the next instruction would be executed
- `jmp/call/ret` changes PC in control transfer

■ In X86-64: `%rip`

Stack-Based Languages

■ Languages that support recursion

- e.g., C, Pascal, Java
- Code must be “Reentrant”
 - Multiple simultaneous instantiations of single procedure
- Need some place to store state of each instantiation
 - Arguments
 - Local variables
 - Return pointer

■ Stack discipline

- State for given procedure needed for limited time
 - From when called to when return
- Callee returns before caller does

■ Stack allocated in Frames (栈帧)

- state for single procedure instantiation

Call Chain Example

```
yoo (...)  
{  
  .  
  .  
  who ();  
  .  
  .  
}
```

```
who (...)  
{  
  . . .  
  amI ();  
  . . .  
  amI ();  
  . . .  
}
```

```
amI (...)  
{  
  .  
  .  
  amI ();  
  .  
  .  
}
```

Procedure **amI ()** is recursive

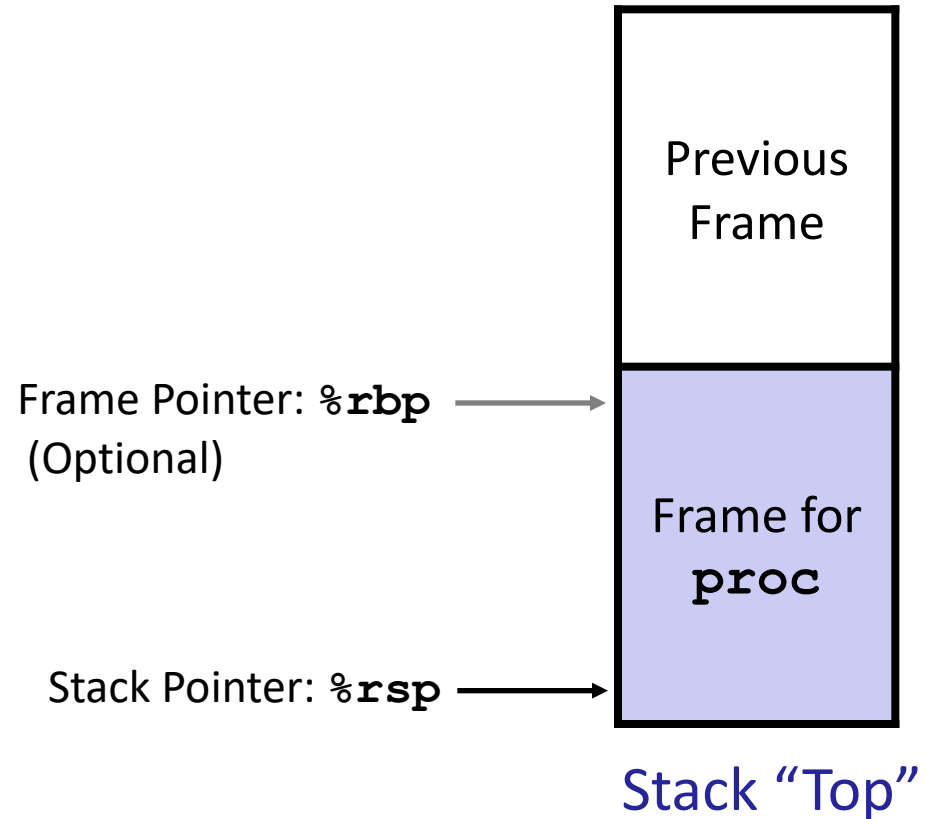

Example

- **Deallocated** when **return**
 - "Finish" code
 - Includes **pop** by **`ret`** instruction

Register Saving Conventions

■ When procedure `yoo` calls `who`:

- `yoo` is the **caller**
- `who` is the **callee**

■ Can register be used for temporary storage?

```
yoo:  
  . . .  
  movq $15213, %rdx  
  call who  
  addq %rdx, %rax  
  . . .  
  ret
```

```
who:  
  . . .  
  subq $18213, %rdx  
  . . .  
  ret
```

- Contents of register `%rdx` overwritten by `who`
- This could be trouble → something should be done!
 - Need some **coordination**

Register Saving Conventions

- When procedure `yoo` calls `who`:
 - `yoo` is the **caller**
 - `who` is the **callee**
- Can register be used for temporary storage?
- Conventions
 - “Caller Saved”
 - Caller **saves** temporary values in its frame **before the call**
 - “Callee Saved”
 - Callee **saves** temporary values in its frame **before using**
 - Callee **restores** them **before returning to caller**

x86-64 Linux Register Usage #1

■ **%rax**

- Return value
- Also caller-saved
- Can be modified by procedure

■ **%rdi, ..., %r9**

- Arguments
- Also caller-saved
- Can be modified by procedure

■ **%r10, %r11**

- Caller-saved
- Can be modified by procedure

Caller-saved

x86-64 Linux Register Usage #2

■ `%rbx`, `%r12`, `%r13`, `%r14`

- Callee-saved
- Callee must save & restore

■ `%rbp`

- Callee-saved
- Callee must save & restore
- May be used as frame pointer
- Can mix & match

■ `%rsp`

- Special form of callee save
- Restored to original value upon exit from procedure

Callee-saved

Callee-Saved Example #1

```
long call_incr2(long x) {  
    long v1 = 15213;  
    long v2 = incr(&v1, 3000);

```

Initial Stack Structure

- X comes in register **%rdi**.

Observations About Recursion

■ Handled **Without Special Consideration**

- **Stack frames** mean that each function call has **private storage**
 - Saved registers & local variables
 - Saved return pointer
- **Register saving conventions** prevent one function call from corrupting another's data
 - Unless the C code explicitly does so (e.g., buffer overflow)
- Stack discipline follows **call / return pattern**
 - If P calls Q, then Q returns before P
 - Last-In, First-Out

■ Also works for **mutual recursion**

- P calls Q; Q calls P

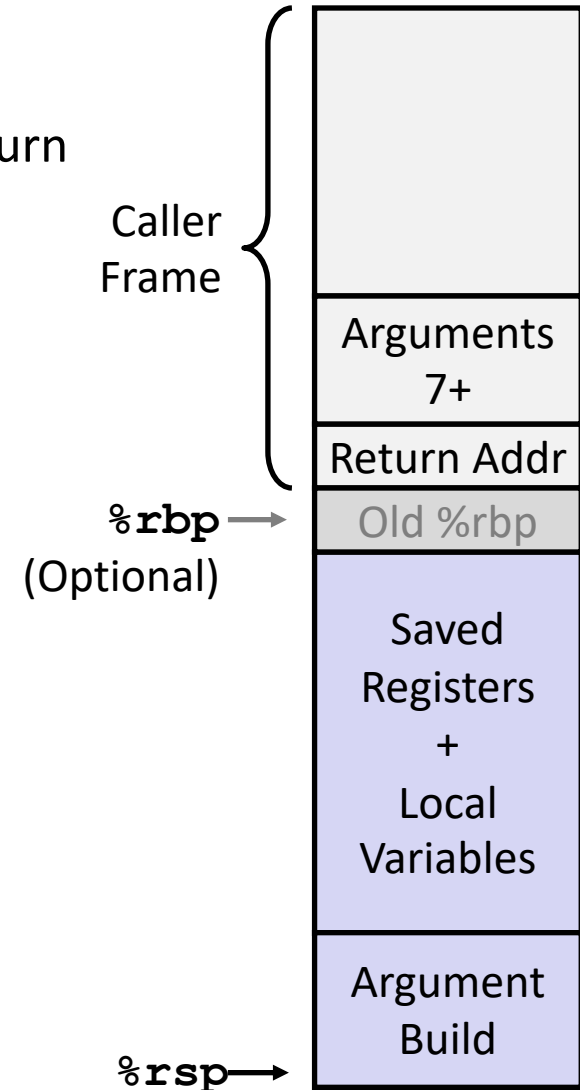

x86-64 Procedure Summary

■ Important Points

- **Stack** is the right data structure for procedure call/return
 - If P calls Q, then Q returns before P

■ Recursion (& mutual recursion) handled by normal calling conventions

- Can safely store values in local stack frame and in callee-saved registers
 - Put function arguments at top of stack
 - Result return in **%rax**
- ## ■ Pointers are addresses of values
- On stack or global

Small Exercise

```
long add5(long b0, long b1, long b2, long b3, long b4) {  
    return b0+b1+b2+b3+b4;  
}  
  
long add10(long a0, long a1, long a2, long a3, long a4, long a5,  
           long a6, long a7, long a8, long a9) {  
    return add5(a0, a1, a2, a3, a4)+  
           add5(a5, a6, a7, a8, a9);

```

- Where are a0,..., a9 passed?
rdi, rsi, rdx, rcx, r8, r9, stack
- Where are b0,..., b4 passed?

- Which registers do we need to save in add10?
